Python Testing Tutorial

Overview

This tutorial helps you to learn automated testing in Python 3 using the `py.test` framework.

Latest version of this book

Challenges

- Challenges
 - 1. Unit Tests
 - 1.1 Test a Python function
 - 1.2 Test proves if code is broken
 - 1.3 Code proves if tests are broken
 - 1.4 Test border cases

Challenges

1. Unit Tests

1.1 Test a Python function

The function `main()` in the module `word_counter.py` calculates the number of words in a text body.

For instance, the following sentence contains **three** words:

```
1. Call me Ishmael
```

Your task is to prove that the `main()` function calculates the number of words in the sentence correctly with **three**.

Use the example test in `test_1_1_unit_test.py`.

1.2 Test proves if code is broken

The test in the module `test_failing_code.py` fails, because there is a bug in the function `word_counter.average_word_length()`. In the sentence

```
1. Call me Ishmael
```

The words are **four**, **two**, and **seven** characters long. This gives an average of:

```
1. >>> (4 + 2 + 7) / 3.0
2. 4.333333333333333
```

Your task is to fix the code, so that the test passes.

Use the example in `test_1_2_broken_code.py`.

1.3 Code proves if tests are broken

The test in the module `test_failing_test.py` fails, because there is a bug in the test file.

Your task is to fix the test, so that the test passes. Use the example in `test_1_3_broken_test.py`.

1.4 Test border cases

High quality tests cover many different situations. The most common situations for the program `word_counter.py` include:

test case	description	example input	expected output
empty	input is valid, but empty	<code>""</code>	0
minimal	smallest reasonable input	<code>"whale"</code>	1
typical	representative input	<code>"whale eats captain"</code>	3
invalid	input is supposed to fail	<code>777</code>	<i>Exception raised</i>
maximum	largest reasonable input	<i>Melville's entire book</i>	<i>more than 200000</i>
sanity	program recycles its own output	<i>TextBody A created from another TextBody B</i>	<i>A equals B</i>
nasty	difficult example	<code>"That #~&%* program still doesn't work!"</code>	6

Your task is to make all tests in `test_1_4_border_cases.py` pass.

Instructions for Trainers

- [Instructions for Trainers](#)
 - [Overview](#)
 - [How to run a course using this toolkit](#)

Instructions for Trainers

Overview

This toolkit helps you to prepare training courses on automated testing in Python. It allows you to create courses with interchangeable

- testing frameworks
- background of participants
- course duration

Our aim is to save you preparation time while leaving room for your own ideas. Most of all, we hope you have fun in your next course.

How to run a course using this toolkit

1. Introduce the Moby Dick Theme to your trainees
2. Copy the code in *code/mobydick* and *code/test_your_framework*.
3. Set the PYTHONPATH environment variable, so that you can do

```
import mobydick
```

4. Share the chapter “Challenges” with your trainees.
5. Share the chapter “Reference” on your test framework with your trainees.
6. Start coding!

Exercise 1: Using a Mock Object

- [Mock Objects](#)
 - [Exercise 1: Using a Mock Object](#)

Mock Objects

Exercise 1: Using a Mock Object

The function `word_report.get_top_words()` requires an instance of the class `TextBody`. You need to test the function, excluding the possibility that the `TextBody` class is buggy. To do so, you need to replace the class by a **Mock Object**, a simple placeholder.

Your task is to write a test for the function `word_counter.get_top_words()` that does not use the class `TextBody`.

Exercise 5: Import test data in multiple test packages

- [Exercise 5: Import test data in multiple test packages](#)

Exercise 5: Import test data in multiple test packages

In a big software project, your tests are distributed to two packages. Both `test_first.py` and `test_second.py` require the variable `MOBYDICK_SUMMARY` from the module `test_data.py`. The package structure is like this:

```
1. testss/  
2.     test_a/  
3.         __init__.py  
4.         test_first.py  
5.     test_b/  
6.         __init__.py  
7.         test_second.py  
8.     __init__.py  
9.     test_data.py  
10.    test_all.py
```

Your task is to make sure that the variable `MOBYDICK_SUMMARY` is correctly imported to both test modules, so that the tests pass for all of:

```
1. tests/test_a/test_first.py  
2. tests/test_b/test_second.py  
3. tests/test_all.py
```

py.test

TO BE DONE

test fixtures and files

py.test tells you temp file paths if test fails.

→ test file not deleted

pytest.org/latest/tmpdir.html

```
1. def test_create_file(tmpdir):  
2.     p = tmpdir.mkdir("sub").join("hello.txt")  
3.     p.write("bla")  
4.     assert p.read() == "content"
```

also see `py.path.local`

test selection

[@slow](#) decorator (see 'patterns & examples')

re-run failed tests

- `pyscaffold` adds a `py.test` mode by default.

Introduction to the unittest Framework in Python

- [Introduction to the unittest Framework in Python](#)
 - [Writing a test class](#)
 - [Running the tests](#)
 - [Testing command-line scripts](#)
 - [Discovering tests](#)
 - [Test data and fixtures](#)
 - [Importing test data in multiple packages](#)

Introduction to the unittest Framework in Python

unittest is a Python framework for writing Unit Tests, Integration Tests, and Acceptance Tests. It mainly provides a class **TestCase** and a **main()** method.

unittest is typically imported with:

```
1. from unittest import TestCase, main
```

Writing a test class

Test classes should extend `TestCase`, and contain at least one method starting with `test_`. Test methods contain assertions.

`TestCase` offers many assertion methods (`assertEqual`, `assertAlmostEqual`, `assertTrue` etc.).

```
1. class AdditionTests(TestCase):
2.
3.     def test_add(self):
4.         self.assertEqual(add(3, 4), 7)
```

Running the tests

The **unittest.main** method will look for all classes derived from `TestCase` that have been imported. It runs all tests inside them and reports.

Typically, you will find `main()` called in a separate code block:

```
1. if __name__ == '__main__':  
2.     main()
```

You can run Python test files with unittest without calling `main()`

```
1. python -m unittest test_file
```

Note: The name of the test module is spelled without `.py`

Testing command-line scripts

To test a command-line script call it using a shell command and redirect the output for further evaluation. The simplest way is to use `os.system`:

```
1. import os  
2. os.system('python myprog.py > out.txt')
```

Discovering tests

```
1. python -m unittest discover
```

Test data and fixtures

The methods `setUp()` and `tearDown()` can be used to prepare testing and clean up afterwards.

Importing test data in multiple packages

When you have many tests distributed to sub-packages, you may want to share test data among them. There are two ways to do so:

Either set the `PYTHONPATH` variable to the directory with your tests.

Alternatively, patch `sys.path` in a local module `test_data.py` in each of the sub-packages, so that they import `../test_data.*`

Warming Up

- Warming Up
 - How many words are in the following sentence?
 - How many words are in the next sentence?
- What is automated testing good for?

Warming Up

How many words are in the following sentence?

```
1. The program works perfectly?
```

You will probably agree, that the sentence contains **four words**.

How many words are in the next sentence?

```
1. That #$$%$* program still doesn't work!\nI already
2. de-bugged it 3 times, and still numpy.array
3. keeps raising AttributeError. What should I do?
```

You may find the answer to this question less obvious. It depends on how precisely the special characters are interpreted.

What is automated testing good for?

Writing automated tests for your software helps you to:

- get clear on what you want the program to do.
- identify gaps in the requirements.
- prove the presence of bugs (**not their absence!**).
- help you during refactoring.

Unit Tests

- [Unit Tests](#)
 - [Exercise 1: Test a Python function](#)
 - [Exercise 2: Test proves if code is broken](#)
 - [Exercise 3: Code proves if tests are broken](#)
 - [Exercise 4: Test border cases](#)

Unit Tests

Exercise 1: Test a Python function

The function `main()` in the module `word_counter.py` calculates the number of words in a text body.

For instance, the following sentence contains **three** words:

```
1. Call me Ishmael
```

Your task is to prove that the `TextCorpus` class calculates the number of words in the sentence correctly with **three**.

Run the example test in `test_unit_test.py` with

```
1. pytest test_unit_test.py
```

Exercise 2: Test proves if code is broken

The test in the module `test_failing_code.py` fails, because there is a bug in the function `word_counter.average_word_length()`. In the sentence

```
1. Call me Ishmael
```

The words are **four**, **two**, and **seven** characters long. This gives an average of:

```
1. >>> (4 + 2 + 7) / 3.0
2. 4.333333333333333
```

Fix the code in `test_broken_code.py`, so that the test passes.

Exercise 3: Code proves if tests are broken

The test in the module `test_broken_test.py` fails, because there is a bug in the test file.

Your task is to fix the test, so that the test passes. Use the example in `test_broken_test.py`.

Exercise 4: Test border cases

High quality tests cover many different situations. The most common situations for the program `word_counter.py` include:

test case	description	example input	expected output
empty	input is valid, but empty	<code>""</code>	0
minimal	smallest reasonable input	<code>"whale"</code>	1
typical	representative input	<code>"whale eats captain"</code>	3
invalid	input is supposed to fail	<code>777</code>	<i>Exception raised</i>
maximum	largest reasonable input	<i>Melville's entire book</i>	<i>more than 200000</i>
sanity	program recycles its own output	<i>TextBody A created from another TextBody B</i>	<i>A equals B</i>
nasty	difficult example	<code>"That #~&%* program still doesn't work!"</code>	6

Your task is to make all tests in `test_border_cases.py` pass.

Fixtures

- [Fixtures](#)
 - [Exercise 1: A module for test data](#)
 - [Exercise 2: Using the fixture](#)
 - [Exercise 3: Create more fixtures](#)
 - [Exercise 4: Fixtures from fixtures](#)

Fixtures

Exercise 1: A module for test data

Create a new module `conftest.py` with a string variable that contains a sentence with lots of special characters:

```
1. sample = """That #&%$* program still doesn't work!
2. I already de-bugged it 3 times, and still numpy.array keeps raising AttributeError. What should
   I do?"""
```

Create a function that returns a `mobydick.TextCorpus` object with the sample text above. Use the following as a header:

```
1. @pytest.fixture
2. def sample_corpus():
3.     ...
```

Exercise 2: Using the fixture

Now create a module `test_sample.py` with a function that uses the fixture:

```
1. def test_sample_text(sample_corpus):
2.     assert sample_corpus.n_words == 77
```

Execute the module with `pytest`. Note that you **do not** need to import `conftest`. Pytest does that automatically.

Exercise 3: Create more fixtures

Create fixtures for the two text corpora in the files `mobydick_full.txt` and

`mobydick_summary.txt` as well.

Exercise 4: Fixtures from fixtures

Create a fixture in `confest.py` that uses another fixture:

```
1. from mobydick import WordCounter
2.
3. @pytest.fixture
4. def counter(mobydick_summary):
5.     return WordCounter(mobydick_summary)
```

Write a simple test that makes sure the fixture is not

None

Parameterized Tests

- [Parameterized Tests](#)
 - [Exercise 1: Sets of example data](#)
 - [Exercise 2: Write another parameterized test](#)

Parameterized Tests

Exercise 1: Sets of example data

You have a list of pairs (word, count) that apply to the text file

`mobydick_summary.txt` :

```
1. PAIRS = [
2.     ('months', 1),
3.     ('whale', 5),
4.     ('captain', 4),
5.     ('white', 2),
6.     ('harpoon', 1),
7.     ('goldfish', 0)
8. ]
```

We will create six tests from these samples.

Instead of creating six tests manually, we will use the **test parametrization in pytest**. Edit the file `test_parameterized.py` and add the following decorator to the test function:

```
1. @pytest.mark.parametrize('word, number', PAIRS)
```

Add two arguments `word` and `number` to the function header and remove the assignment below.

Run the test and make sure all six tests pass.

Exercise 2: Write another parameterized test

The function `get_top_words()` calculates the most frequent words in a text corpus. It should produce the following top five results for the book `mobydick_full.txt`:

position	word
1.	of
2.	the
3.	is
4.	sea
5.	ship

Write one parameterized test that checks these five positions.

Testing Command-Line Programs

- [Testing Command-Line Programs](#)
 - [Exercise 1: Test a command-line application](#)
 - [Exercise 2: Test command-line options](#)
 - [Exercise 3: User Acceptance](#)

Testing Command-Line Programs

Exercise 1: Test a command-line application

The program `word_counter.py` can be used from the command line to calculate the most frequent words with:

```
1. python word_counter.py moby dick_summary.txt
```

Command-line applications need to be tested as well. You find tests in `test_commandline.py`.

Your task is to make sure the command-line tests pass.

Exercise 2: Test command-line options

The program `word_counter.py` calculates most frequent words in a test file. It can be used from the command line to calculate the top five words:

```
1. python word_counter.py moby_dick_summary.txt 5
```

Your task is to develop a new test for the program.

Exercise 3: User Acceptance

The ultimate test for any software is whether your users are able to do what they need to get done.

Your task is to *manually* use the program `word_counter.py` to find out whether Melville used *'whale'* or *'captain'* more frequently in the full text of the book *"Moby Dick"*.

The User Acceptance test cannot be replaced by a machine.

Test Suites

- [Test Suites](#)
 - [Exercise 1: Test collection](#)
 - [Exercise 2: Options](#)
 - [Exercise 3: Fixing tests](#)
 - [Exercise 4: Test selection](#)

Test Suites

Exercise 1: Test collection

Run all tests written so far by simply typing

```
1. pytest
```

Exercise 2: Options

Try some options of pytest:

```
1. pytest -v # verbose output
2.
3. pytest -lf # re-run failed tests
4.
5. pytest -x # stop on first failing test
```

Exercise 3: Fixing tests

Fix the tests in `test_suite.py`

Exercise 4: Test selection

Run only one test class

```
1. pytest test_suite.py::TestAverageWordLength
```

or a single test function:

```
1. pytest test_suite.py::TestAverageWordLength::test_average_words
```

Your task is to run only the function `test_word_counter.test_simple` from the test suite in `tests/`.

Test Coverage

- [Test Coverage](#)
 - [Exercise 1: Calculate Test Coverage](#)
 - [Exercise 2: Identify uncovered lines](#)
 - [Exercise 3: Increase test coverage](#)

Test Coverage

For the next exercises, you need to install a small plugin:

```
1. pip install pytest-cov
```

Exercise 1: Calculate Test Coverage

Calculate the percentage of code covered by automatic tests:

```
1. pytest --cov
```

Exercise 2: Identify uncovered lines

Find out which lines are not covered by tests. Execute

```
1. coverage html
```

And open the resulting `htmlcov/index.html` in a web browser.

Exercise 3: Increase test coverage

Bring test coverage of `word_counter.py` to 100%.

Testing New Features

- [Testing New Features](#)
 - [Exercise 1: Add new feature: special characters](#)
 - [Exercise 2: Add new feature: ignore case](#)
 - [Exercise 3: Add new feature: word separators](#)

Testing New Features

Exercise 1: Add new feature: special characters

Add a new feature to the `word_counter.py` program. The program should remove special characters from the text before counting words.

Your task is to prove that the new feature is working.

Exercise 2: Add new feature: ignore case

Add a new feature to the `word_counter.py` program. The program should ignore the case of words, e.g. `'captain'` and `'Captain'` should be counted as the same word.

Your task is to prove that the new feature is working.

Exercise 3: Add new feature: word separators

The program `word_counter.py` does separate words at spaces, but not tabulators. You need to change that.

The following sentence should also contain **four** words:

```
1. The\tprogram\tworks\tperfectly.
```

Your task is to add a test for this new situation and make it work.

Theme: Counting Words in Moby Dick

Counting Words in Moby Dick

Moby Dick: Plot synopsis

Captain Ahab was vicious because Moby Dick, the white whale, had bitten off his leg. So the captain set sail for a hunt. For months he was searching the sea for the white whale. The captain finally attacked the whale with a harpoon. Unimpressed, the whale devoured captain, crew and ship. The whale won.

word frequencies

whale 

captain 

harpoon 

Video

[Moby Dick short synopsis on Youtube](#)

Course Objective

Herman Melville's book *"Moby Dick"* describes the epic fight between the captain of a whaling ship and a whale. In the book, the whale wins by eating most of the other characters.

But does he also win by being mentioned more often?

In this course, you have a program that analyzes the text of Melville's book.

You will test whether the program work correctly?

Why was this example selected?

Three main reasons:

- The implementation is simple enough for beginners.
- Counting words easily yields different results (because of upper/lower case, special characters etc). Therefore the program needs to be thoroughly tested.
- You can easily change the theme to another book from [Project Gutenberg](#).

Lesson Plan for a 45' tutorial

Recap Puzzle

- [Recap Puzzle](#)

Recap Puzzle

The rows in the table got messed up!

Match the test strategies with the correct descriptions.

test strategy	description
Unit Test	files and examples that help with testing
Acceptance Test	collection of tests for a software package
Mock	relative amount of code tested
Fixture	tests a single module, class or function
Test suite	prepare tests and clean up afterwards
Test data	replaces a complex object to make testing simpler
Test coverage	tests functionality from the users point of view

This exercise works better when each element from the table is printed on a paper card.
